

CmpE 260 - Principles of Programming Languages

Spring 2025 - Project

Deadline: 01 June 2025 23:59

Assistant: Berrenur Saylam
berrenur.saylam@bogazici.edu.tr

1 Introduction

In this project, you will develop a simulation for a farm environment where animals can move around, consume food, and reproduce. The game takes place in a simplified, farm-themed world where reaching sufficient energy points from foods allows animals to reproduce.

2 Knowledge Base

We have built the basic mechanics for you in `cmpefarm.pro` and `farm.pro`. These files should remain unchanged. The farm map is provided in `farm.txt`. You can change it to test your farm environment in different settings.

The main data structure for this project is given in `state/2` predicate. After you load your main file (`main.pro`), you can check the current state with the following query:

```
?- state(Agents, Objects).  
Agents = agent_dict{0:agents{children:0, energy_point:0, subtype:cow, type:herbivore, x:10, y:1}, ...},  
Objects = object_dict{0:object{subtype:grain, type:food, x:5, y:2}, ...},
```

This state is generated from the map file `farm.txt`. Each character in the `farm.txt` represents different types of agents and objects:

- Agents
 - C: Cow.
 - H: Chicken.
 - W: Wolf.
- Objects
 - G: Grass.
 - F: Grain.
 - M: Corn.

Each agent is characterized by six distinct attributes: `subtype`, `type`, `children`, `energy_point`, `x`, `y`. Agents are able to move through the map and can eat food to increase their energy points. If the agent's energy point exceeds a certain point, the agent reproduces and the number of agents increases. The generated agent will be positioned at a coordinate in a clockwise order.

- **subtype**: Species of the agent.
- **type**: Agent's type (herbivore/carnivore).
- **children**: Number of children the agent has.
- **energy_point**: Agent's energy for reproduction.
- **x**: X coordinate of the agent.
- **y**: Y coordinate of the agent.

Each object is represented by four attributes, **subtype**, **type**, **x**, **y**, and they are held in an object dictionary.

- **subtype**: Object's kind.
- **type**: Object's type.
- **x**: X coordinate of the object.
- **y**: Y coordinate of the object.

The agents can move in a certain direction, eat and reproduce. Cows have the ability to move in four directions: **up**, **down**, **left** and **right**, allowing them to navigate the game map within these specific constraints. Chickens in the game are restricted to moving diagonally; they can move **up-right**, **up-left**, **down-right**, and **down-left**. Lastly, wolves can move in every direction. A wolf can move to any tile except one already occupied by another wolf. Herbivores, on the other hand, can only move to tiles that are unoccupied by any animal.

Moreover, cows in the game are able to eat **grass** and **grain**, but they cannot consume **corn**. Chickens can eat **grain** and **corn**, but they are not able to eat **grass**. If the agent reaches the location of the food, it does not automatically consume it, instead wait for the eat command.

3 Predicates

3.1 `agents_distance(+Agent1, +Agent2, -Distance)` 10 points

This predicate will compute the Manhattan distance(D) between two agents.

$$D([x_1, y_1], [x_2, y_2]) = |x_1 - x_2| + |y_1 - y_2| \quad (1)$$

All test cases will contain a valid **Agent1** and **Agent2** for this predicate.

Examples:

```
?- state(Agents, _), agents_distance(Agents.0, Agents.1, Distance)
Distance = 10.
```

```
?- state(Agents, _), agents_distance(Agents.1, Agents.2, Distance)
Distance = 4.
```

3.2 `number_of_agents(+State, -NumberOfAgents)` 10 points

This predicate finds the total number of agents in a **State** and unifies it with **NumberOfAgents**. **State** is a list in the form of **[Agents, Objects]**.

Examples:

```
?- state(Agents, _), number_of_agents([Agents, _], NumberOfAgents).
NumberOfAgents = 4
```

3.3 `value_of_farm(+State, -Value)` 10 points

This predicate calculates the total value of all products on the farm. You need to consider the values of agents (animals) and objects (foods). You can find the values of products in `farm.pro`.

Examples:

```
?- state(Agents, Objects), value_of_farm([Agents, Objects], Value).  
Value = 1200
```

3.4 `find_food_coordinates(+State, +AgentId -Coordinates)` 10 points

This predicate will find the coordinates of the foods consumable by the specific Agent at the given `State` and unifies the list of coordinates with `Coordinates`. If there is no such object that can be eaten by the agent, the predicate should be `false`.

Examples:

```
?- state(Agents, Objects), find_food_coordinates([Agents, Objects], 0, Coordinates).  
Coordinates = [[5, 2], [3, 3], [9, 5], [1, 6]].
```

```
?- state(Agents, Objects), find_food_coordinates([Agents, Objects], 2, Coordinates).  
Coordinates = [[5, 2], [6, 5]]
```

```
?- state(Agents, Objects), find_food_coordinates([Agents, Objects], 4, Coordinates).  
false.
```

3.5 `find_nearest_agent(+State, +AgentId, -Coordinates, -NearestAgent)` 10 points

This predicate finds the nearest agent and unifies the agent's coordinate with `Coordinates` in the `[X,Y]` form, and unifies the agent's dictionary with `NearestAgent`.

You **cannot** use the `->` operator for this or any associated helper predicates.

Examples:

```
?- state(Agents, Objects), find_nearest_agent([Agents, Objects], 0, Coordinates, NearestAgent).  
Coordinates = [10,6]  
NearestAgent = agents{children:0, energy_point:0, subtype:cow, type:herbivore, x:10, y:6}.
```

```
?- state(Agents, Objects), find_nearest_agent([Agents, Objects], 3, Coordinates, NearestAgent).  
Coordinates = [2,5]  
NearestAgent = agents{children:0, energy_point:0, subtype:chicken, type:herbivore, x:2, y:5}
```

3.6 `find_nearest_food(+State, +AgentId, -Coordinates, -FoodType, -Distance)` 10 points

This predicate finds the nearest **consumable** food by the Agent and unifies the object's coordinate with `Coordinates` in the `[X,Y]` form, unifies the kind of the food with `FoodType`, and unifies the Manhattan distance between the food and the agent with `Distance`. If there is no such object that can be eaten by the agent, the predicate should be `false`.

Examples:

```
?- state(Agents, Objects), find_nearest_food([Agents, Objects], 1, Coordinates, FoodType, Distance).  
Coordinates = [2,5]  
FoodType = chicken  
Distance = 4
```

3.7 `move_to_coordinate(+State, +AgentId, +X, +Y, -ActionList, +DepthLimit)` 10 points

This predicate will find a series of actions that could get the Agent to a specific [X,Y] coordinate and unify this list of actions with ActionList. The number of actions is limited with the DepthLimit.

Examples:

```
?- state(Agents, Objects), move_to_coordinate([Agents, Objects], 1, 1, 5, ActionList, 4).
ActionList = [move_down, move_down, move_down]

?- state(Agents, Objects), move_to_coordinate([Agents, Objects], 3, 10, 5, ActionList, 7).
ActionList = [move_left, move_up, move_up, move_up, move_down, move_down, move_right]

?- state(Agents, Objects), move_to_coordinate([Agents, Objects], 2, 10, 6, ActionList, 4).
false.
```

3.8 `move_to_nearest_food(+State, +AgentId, -ActionList, +DepthLimit)` 10 points

This predicate will find a series of actions that will get the Agent to the closest food that can be consumed by the Agent and unify this list of actions with ActionList. The number of actions is limited with the DepthLimit.

Examples:

```
?- state(Agents, Objects), move_to_nearest_food([Agents, Objects], 1, ActionList, 3).
ActionList = [move_down, move_down_right, move_down]

?- state(Agents, Objects), move_to_nearest_food([Agents, Objects], 0, ActionList, 4).
false.
```

3.9 `consume_all(+State, +AgentId, -NumberOfMovements, -Value, -NumberOfChildren, +DepthLimit)` 20 points

This predicate will find a sequence of actions that will guide the Agent to every consumable and reachable food item, beginning with the closest one.

- After reaching the first item, the agent should **consume** the item.
- The agent should find the next nearest consumable item and move towards it.
- If the nearest item cannot be reached by the agent, the agent should move towards to the next closest item.
- The number of actions is limited by the DepthLimit; however, you are expected to reach the item using the smallest number of movements possible.
- There will be no consumable items at the same distance from the agent.
- You should first check whether the specific agent can **consume** the item and can **move** to the item's location.

Unify the total number of movements with NumberOfMovements and farm's new value with Value and the total number of children of the agent with NumberOfChildren.

Examples:

```
?- state(Agents, Objects), consume_all([Agents, Objects], 1, NumberOfMovements, Value, NumberOfChildren, 10).
NumberOfMovements = 16
Value = 100
NumberOfChildren = 1

?- state(Agents, Objects), consume_all([Agents, Objects], 0, NumberOfMovements, Value, NumberOfChildren, 8).
NumberOfMovements = 20
Value = 2110
NumberOfChildren = 2
```

3.10 Printing states

You can use `make_one_action/4` with `print_state/1` to view the new state after the action.

Moreover, you can use `make_one_action_print/4` and `make_series_of_actions_print/3` to make some actions and view the final state.

For example,

```
?- state(Agents, Objects), make_one_action(Action, [Agents, Objects], AgentId, NewState),  
print_state(NewState).
```

This will help you see the actions of the agent, and hopefully allow you to debug more easily.

4 Documentation

Please include explanatory comments in your code to clarify the purpose of each predicate. Code submissions without comments may lose points if any predicate is difficult to understand.

In addition to the code, you are required to submit a brief report in PDF format that outlines your ideation process, implementation steps, challenges encountered, and lessons learned throughout the project. The report should be clear, concise, and no longer than 3 pages. This report must be written in your own words. AI-generated or plagiarized content is strictly prohibited. Submissions without a report will not be evaluated; the code section will automatically receive zero points.

5 Submission

You will submit two files: your code in a single file named `main.pro` and a separate report document. The entire code must be contained within `main.pro`. First four lines of your `main.pro` file must have exactly the lines below since it will be used for compiling and testing your code automatically:

```
% name surname  
% student id  
% compiling: yes  
% complete: yes
```

The third line denotes whether your code compiles correctly, and the fourth line denotes whether you completed all of the project, which must be `no` if you're doing a partial submission. This whole part must be lowercase and include only the English alphabet. Example:

```
% ayse yilmaz  
% 2021234567  
% compiling: yes  
% complete: yes
```

6 Tips and Tricks

Although the project may seem long at the first glance, it can be done in a reasonable amount of time. Therefore, do not panic. Before starting, please carefully examine `cmpefarm.pro` and `farm.pro`. It might be also useful to first run a hard-coded action list, then think about how to generate that action list.

- Do not rush. First think about the requirements, what you need, how you can solve it in a modular way. If you can verbally describe your needs, you can probably implement it easily.
- Try to formalize the problem, then try to convert the logic formulate to Prolog.
- You can use `findall/3`, `bagof/3` or `setof/3`.
- You are not allowed to use `assert/1` and `retract/1`.
- You can use extra predicates. The ones given above are compulsory.
- If a predicate becomes too complex, either divide it into some predicates or take another approach. Use debugging (through `trace/1`), approach your program systematically.
- If you do not want to see certain variables, you can use `set_prolog_flag/2` predicate.
`set_prolog_flag(toplevel_print_anon, false)` ensures that variables starting with `_` are not printed in the output.
